The evolution of structures in the universe

Andreas Ellewsen[1]

[1] Institute of Theoretical Astrophysics, University of Oslo, P.O. Box 1029 Blindern, N-0315 Oslo, Norway

Abstract. I compute the density perturbations, and velocities of dark matter and baryons. As well as the gravitational potential Φ and curvature Ψ. More importantly I also find the temperature multi poles Θ_l.

0.1   Introduction

In this project I am following the algorithm presented in Callin (2005)[1] for simulating the cosmic microwave background. This is part three of four for this project.

In the first part I set up the background cosmology of the universe, and made a function that could find the conformal time as a function of x. In the second part I computed the electron fraction, electron density, optical depth and visibility function for times around and during recombination.

In this part I will use some of these functions along with the Einstein-Boltzmann equations without polarization and neutrinos to compute the density perturbations, and velocities of dark matter and baryons. I will also compute the temperature multi poles Θ_l.

As previously done I will continue building on the skeleton code provided.

0.2 Equations

The full set of Einstein-Boltzmann equations without polarization and neutrinos read

$$\Theta_0' = -\frac{ck}{\mathcal{H}}\Theta_1 - \Phi' \tag{1}$$

$$\Theta_1' = \frac{ck}{3\mathcal{H}}\Theta_0 - \frac{2ck}{3\mathcal{H}}\Psi + \tau'\left[\Theta_1 + \frac{1}{3}v_b\right] \tag{2}$$

$$\Theta_l' = \frac{lck}{(2l+1)\mathcal{H}}\Theta_{l-1} - \frac{(l+1)ck}{(2l+1)\mathcal{H}}\Theta_{l+1} + \tau'\left[\Theta_l - \frac{1}{10}\Theta_l\delta_{l,2}\right], 2 \leq l < l_{max} \tag{3}$$

$$\Theta_l' = \frac{ck}{\mathcal{H}}\Theta_{l-1} - c\frac{l+1}{\mathcal{H}\eta(x)}\Theta_l + \tau'\Theta_l, l = l_{max} \tag{4}$$

$$\delta' = \frac{ck}{\mathcal{H}}v - 3\Phi' \tag{5}$$

$$v' = -v - \frac{ck}{\mathcal{H}}\Psi \tag{6}$$

$$\delta_b' = \frac{ck}{\mathcal{H}}v_b - 3\Phi' \tag{7}$$

$$v_b' = -v_b - \frac{ck}{\mathcal{H}}\Psi + \tau'R(3\Theta_1 + v_b) \tag{8}$$

$$\Phi' = \Psi - \frac{c^2k^2}{3\mathcal{H}^2}\Phi + \frac{H_0^2}{2\mathcal{H}^2}\left[\Omega_m a^{-1}\delta + \Omega_b a^{-1}\delta_b + 4\Omega_r a^{-2}\Theta_0\right] \tag{9}$$

$$R = \frac{4\Omega_r}{3\Omega_b a}. \tag{10}$$

These equations are the ones we will use when we are not in the tight coupling regime. When in the tight coupling regime the factor $(3\Theta_1 + v_b)$ is very close to zero. In the equation for v_b' this is multiplied by τ' which is very large in, making this equation terribly unstable. The same thing makes the equation for Θ_1' unstable. Because of this one can expand $(3\Theta_1 + v_b)$ in powers of $1/tau'$. This results in a slight change in the set of equations for v_b' and Θ_l.

$$q = \frac{-[(1-2R)\tau' + (1+R)\tau''](3\Theta_1 + v_b) - \frac{ck}{\mathcal{H}}\Psi + (1 - \frac{\mathcal{H}'}{\mathcal{H}})\frac{ck}{\mathcal{H}}(-\Theta_0 + 2\Theta_2) - \frac{ck}{\mathcal{H}}\Theta_0'}{(1+R)\tau' + \frac{\mathcal{H}'}{\mathcal{H}} - 1} \tag{11}$$

$$v_b' = \frac{1}{1+R}\left[-v_b - \frac{ck}{\mathcal{H}}\Psi + R(q + \frac{ck}{\mathcal{H}}(-\Theta_0 + 2\Theta_2) - \frac{ck}{\mathcal{H}}\Psi)\right] \tag{12}$$

$$\Theta_1' = \frac{1}{3}(q - v_b'). \tag{13}$$

So far I have not stated what tight coupling means. Basically because of the mathematical operations we have done, like expanding in powers of $1/\tau'$, we end up with some conditions on when these equations above can be used. The conditions are $|ck/(\mathcal{H}\tau')| < 1/10$, that the time is before recombination, and $|\tau'| > 10$.

All of these equations refer to their respective quantities in Fourier space. This means that the k's everywhere refer to Fourier modes. This is done to separate the quantities into the different scales at which they take place, with low k's referring to large scales, and high k's to small scales.

Because of this it is expected that quantities relating to large k's start changing earlier than those relating to low k's, simply because no causal physics has been able to work on such large scales.

0.3   Implementation

The way to solve all these equations is to first make a function that finds the time where tight coupling ends. Note that this function clearly depends on which k mode we are working on.

For each k we insert the initial conditions, and then run through every value of x from some start value early in the universe after inflation is done. In this case I have chosen to use the x value corresponding to $a_{init} = 10^{-8}$. At some point through this the x value becomes larger than the x at the end of tight coupling. At that point we change the equations for the relevant quantities, and continue on until we reach today. This has to be done for all k values. I have chosen to set the limit at $k = 100$ so far. With this low k value the program completes in about 3 minutes.

It should also be said that we limit our number of l's to 6. This can be done because we are using line of sight integration. Historically people used to include thousands of variables to trace multi poles. If we had to use this the program would use days or weeks instead of minutes.

0.4   Results

To get a good distribution of k modes we use a quadratic distribution in k such that

$$k_i = k_{min} + (k_{max} - k_{min})(i/100)^2, \tag{14}$$

where $k_{max} = 1000H_0/c$, and $k_{min} = 0.1H_0/c$. The results show the various quantities for six different k values. These k values are k_1, k_5, k_{10}, k_{40}, k_{60}, and k_{100}. See figures 1a and 1b for Φ and Ψ. Figures 2a, and 2b for δ, and δ_b. Figures 3a, and 3b for v and v_b. And figure 4 for Θ_0. Most of what is happening is explained in the captions for each of them.

0.5   Conclusions

In this project we have calculated the density perturbations and velocities of dark matter and baryons. We also found the gravitational potential Φ and curvature Ψ. And most importantly we found the evolution of the temperature multi poles Θ_l which will enable us to make a CMB power spectrum in the next and final part of the project. We saw that dark matter and regular matter behaved as one would expect considering their respective properties with regards to electromagnetic radiation. This caused the gravitational potential to decrease when the dark matter density increased. This also meant that the curvature increased accordingly. All of these contributed to the calculation of the temperature multi poles, of which we only plotted Θ_0 at this point. We saw that the different modes stabilized at different temperatures. Exactly why the mean temperature of different Fourier modes should do this is not obvious at this point.

I was also able to appreciate the power of precomputing certain quantities, this enabled me to speed up the program by a factor of 10. There is still potential for improvement on this part, but it is good enough for its purpose at this point. If at a later point there is a need to increase the number of Fourier modes one should look at more quantities to precompute to reduce the runtime further. There is also some indication that the x grid used may benefit from a bit finer resolution when looking at the higher modes in Θ_0.

0.6   References

[1] P. Callin, astro-ph/0606683
(a) The plot for Φ for six different k's.
(b) The plot for Ψ for six different k's.

Figure 1: The first thing to note is that the plots seem to be the inverse of each other. Also all the modes of Φ start at 1, and decrease as they leave tight coupling. The higher the mode, the closer to 0 they stabilize after recombination. The higher modes oscillate a bit before stabilizing around recombination. This is not seen in the lower modes. The smallest modes do not show this oscillating behavior at all, instead they slowly decrease after tight coupling before doing a nose dive near the end. The behavior of Ψ is the complete inverse of this. This behavior is as expected since the gravitational potential should be high with things far apart, and small when they are close. Thus higher modes fall first since matter and dark matter for high modes can clump together earlier, shrinking the potential. (Dark matter is the dominant factor here since matter is prevented from clumping by the photons until later.) This of course creates curvature, and that is why we see the opposite effect for Ψ. The lowest modes simply have not had time to collapse as much as they can yet.
(a) The plot for δ for six different k's.
(b) The plot for δ_b for six different k's.

Figure 2: Note the special y axis on the plot for δ_b. The dark matter perturbations behave nicely. The higher the mode the earlier it can start growing, just as expected due to the fact that forces don't propagate instantaneously. Note also that all the dark matter perturbations remain positive. This is not the case for baryons. When we start approaching recombination all the higher order modes start oscillating, and it is only after recombination is done that they are allowed to start growing again, and now they can behave like dark matter. The reason for this is of course that dark matter does not interact with electromagnetic radiation while regular matter does. Thus dark matter has no other force than gravity acting on it and thus it can collapse even though the universe is dominated by radiation. This is not the case for regular matter, as we see in the plot. The radiation rips everything apart before it can grow large, causing it to oscillate until recombination lets the photons loose.

5

(a) The plot for v for six different k's.
(b) The plot for v_b for six different k's.

Figure 3: As before there is a clear difference between the velocities of the two components. The highest modes start growing first, and since they are larger when approaching recombination they slow down more. Note the yellow and purple curves in the v plot. The lower modes don't slow down, but they don't increase as fast, while the smallest modes don't notice anything special happening. The velocity of the baryons is very different. As the dark matter, the highest modes start growing first, but as they exit tight coupling they start to oscillate, expanding and contracting, until after recombination where they speed up again to catch up with the dark matter. Note that the lowest modes don't notice anything special happening here either. In fact, they are fairly equal for dark matter and baryons. All of this has the same explanation as for the density perturbations. This is after all the velocity of those perturbations.
Figure 4: The plot shows Θ_0 for six different k's. The low modes stay constant until the time at which their corresponding baryon perturbations start growing. This is as expected since Θ_0 measures the mean temperature, and this should increases as baryons clump together because of gravity. The high modes oscillate like their corresponding perturbation modes do. However, they do not grow after recombination, instead they stabilize around values fairly close to zero. The intermediate modes like k_{10} oscillate around some value between 0.5 and 1.
